Abstract— In this paper the authors propose a web application oriented on business to business (B2B) and internet automotive marketing. The study case is related to an industrial project concerning tires recognition application and real time comparison of prices of competitors. By means of a smartphone camera able to identify and classify car plates, the system provides different associations of compatible tires for a specific car model and the best prices. The frontend system is based on Optical Character Recognition (OCR) method and the backend works on automatic extraction of competitor prices from different databases and from internet network. The dynamic pricing is due to the best price choice related to period of car plate recognition. The price choice is supported by data mining processing performed by a k-Means workflow. The paper summarizes the results of a research industrial project. The used approaches could be used for different automotive applications involving market of different car parts.

Keywords— Web Application, Mobile Marketing, OCR, Tires detection, Dynamic Pricing, Data Mining, K-Means.

I. INTRODUCTION

Different studies focused the attention on dynamic pricing in marketing and business [1]-[6]. The strategy to adopt changes with the application and with the typology of market. E-commerce and in general internet are powerful tools useful to adopt a strategy [7], to decrease price competition [8] and to provide customer motivation [9]. For this purpose internet channels could be data sources useful for real time monitoring of prices. The goal of the study is the matching between software tools oriented on online dynamic pricing and mobile ones able to acquire information about products to analyze. In fact the mobile technologies represents a “smart way” to recognize objects stored in a database. In particular, by considering automotive applications, some technique [10]-[12] could recognize care plates in order to attain data about car models, car proprietary, tires compatibility and so on. An approach used to recognize car plates is the Optical Character Recognition (OCR) which could be implemented by using techniques such as Automatic Number Plates Recognition (ANPR) [13] and suitable libraries as OpenCV [14]. According to these topics has been developed the conceptual model of Fig. 1, which is summarized in the following main requirements:

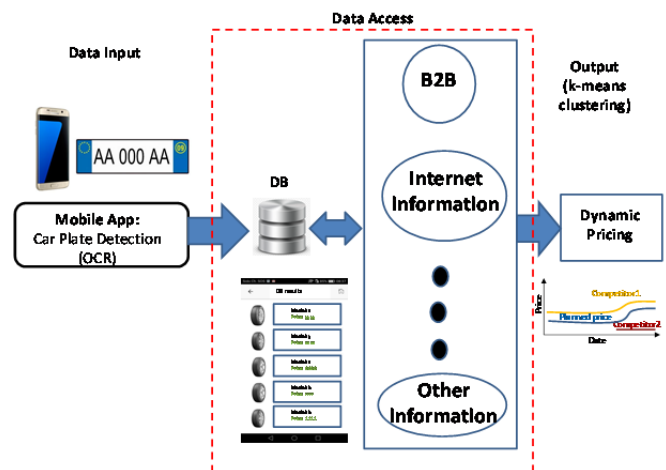

Fig. 1. Functional diagram of the proposed model.

- i. An user detect the a car plates by means of a mobile app and by OCR algorithm (automatic OCR detection or manual data entry);
- ii. The plate is recognized and a database provides a list of possible tires correlated with the car model;
- iii. Different data available in internet or in B2B platforms about tires prices are compared: this comparison will provide a full dashboards of competitor prices;
- iv. Data are collected and a data mining algorithm will provide a Decision Support System (DSS) about the best cluster and price to adopt (dynamic pricing updating with actual tires price and comparisons with competitors prices).

As shown in Fig. 1, the prototype system is structured in the following three main parts:

- 1) A frontend interface (mobile APP);
- 2) A backend system for data access and for the check of tires availability;
- 3) A data mining engine for dynamic pricing outputs.

Concerning data mining algorithms K-means approach is useful for data clustering thus providing a simple way to perform a DSS [15] by implementing data processing workflows by means of graphical user interfaces (GUIs) [16].

We will discuss in the next sessions the architecture and system design, the backend/front-end specifications of the prototype system, and, finally, a simulation of the dynamic pricing output.

II. SYSTEM DESIGN AND BACK/FRONT END FRAMEWORKS

In this section we will provide the whole design of the proposed project sketched in the basic architecture of Fig.1. In order to propose a full design scheme, different layouts of diagrams were illustrated. Unified Modeling Language (UML) has been used for the design layouts (UMLet tool). The design is divided in the following five layouts:

1. Use Case Diagram (UCD): in Fig. 2 is shown the UCD diagrams identifying the actors of the proposed model (customer is the actor having the car plate to detect, besides “visualization” is the user which utilize the OCR mobile application and the dynamic pricing analysis);
2. Activity Diagram (AD): in Fig. 3 is illustrated the flow chart concerning the main steps of the process of the tires detection, car model compatibility, and check of warehouse availability (main functions of the proposed model);
3. Class diagrams (CD): in Fig. 4 is sketched the structure of the prototype system by showing the system's classes, their attributes, operations and methods, and the relationships among objects (the CD include the classes of the backend and of the frontend systems);
4. Sequence Diagram (SD) B2B data access: Fig. 5 indicates the time sequence of the DB connection and query management process.
5. Sequence diagram (SD) input system: Fig. 6 explains the time sequence related to the mobile application (photo acquisition, manual data entry of the plates, OCR usability).

Fig. 2. Use Case Diagram of the project (UCD).

The full logic of the prototype architecture of Fig. 1 is developed in the diagrams of Fig. 2, Fig. 3, Fig. 4, Fig. 5 and Fig. 6. All diagrams were optimized after the testing phase therefore satisfy all the requirements.

The framework used for the development of Android/Windows/IoS mobile APP is the platform integrating Ionic2, Angular 2 and Apache Cordova tools. The backend has been implemented by following the client/web service logic (http request/http response) accessing to the database by API. For the backend implementation it has been used Magento (based to Zend php framework) API and extended with new functionalities (for mobile app synchronization and price comparison). For the OCR plate recognition it has been developed an algorithm based on OpenALPR libraries. OpenALPR is an open source Automatic License Plate Recognition library written in C++ with bindings in C#, Java, Node.js, Go, and Python. The library analyses images and video streams to identify license plates. The output is the text representation of any license plate characters. OpenALPR requires the following additional libraries: Tesseract OCR and OpenCV. For the visualization of tires price of competitors has been implemented Rapid Miner tools reading an excel file, besides for data mining processing has been implemented an object workflow of KNIME Studio tools (clustering processing by k-Means algorithm). KNIME and Rapid Miner are open source data analytics, reporting and integrating various components for machine learning and data mining through their modular data pipelining concept (workflow). Graphical user interfaces (GUIs) allow assembly of nodes for data preprocessing (Extraction, Transformation, Loading –ETL–), for modeling and data analysis and visualization (reporting). Both the approach are high level programming tools and can be considered as SAS (Software as A Service) alternative. We observe that Rapid Miner offers a best Scattering Multiple reporting operator useful to compare together all the tires prices of more competitors.

III. TESTING AND RESULTS

Different tests have been performed for the mobile APP. We describe below five main performed test:

- First test (Fig. 7): access to the system (login), photo menu (shot a photo, photo menu);
- Second test (Fig. 8): shot a car plate photo, processing (OCR algorithm), detection accuracy (probabilistic percentage of correct plates detection: in the figure is indicated an accuracy of the 90 % for the test plate);
- Third test (Fig. 9): manual data entry of the car plates, search by car function, search car by model function;
- Fourth test (Fig. 10): show tire details, show list of tires prices, advanced research function (by tires parameters provided by the database system);
- Fifth test (Fig. 11): buy/order function, tire model/car model compatibility, selection of season for the tires choice.

The backend test has been focused on modifying of price field, on the data entry of competitor price and on the bidirectional linking with the frontend system. In Fig. 12 we illustrate a screenshot related to the adding procedure of a single price. The backend system is able to export data file in csv/excel format. These files will be processed by the data mining workflows. In order to check quickly the data mining workflow output, we have constructed the test Excel input file of Fig. 13: the file indicates randomic values of 44 types of tires model, the related prices of 4 main competitors, and the quantity sold by each competitor. In order to view the global price distribution of all tire models we used the “Scatter Multiple” function of Rapid Miner Tool (see Fig. 14): specifically we imported the testing file by means of the “Read Excel” object and by executing a basic input/output workflow (see inset of Fig. 14 where the object is linked by a “pipeline” to the input and to the output port). By running the basic workflow, and by selecting the “Scattering Multiple” function after the simulation, it is possible to plot all the tires prices (see graphical report of Fig. 14). By selecting the sold quantities will be possible to plot also the sold quantities distribution. The scattering multiple function is a first level analysis able to suggest a price according with competitoe trends. For a deeply analysis (second level analysis) we need of an advanced data mining algorithm. In this case of study we consider the k - means algorithm by setting k =5 (five cluster to evaluate). The algorithm was implemented by a KNIME object. This object outputs the cluster centers for a predefined number of clusters (no dynamic number of clusters, the dynamic price is to think as an updating of competitors dataset to analyze). K-Means performs a crisp clustering that assigns a data vector to exactly one cluster. The algorithm terminates when the cluster assignments do not change anymore. The clustering algorithm uses the Euclidean distance on the selected attributes. The data is not normalized by the “k -Means” object (if required, should be considered to use the “Normalizer” as a preprocessing step). For four competitors to analyze, five cluster are enough for data processing (five price levels matched with five level of

quantities of sold tires). By decreasing the number of clusters the analysis could be poor for valid supporting decisions.

three objects: i) “Excel reader (XLS)” able to import the input file of Fig. 13; ii) “k-Means” object implementing k – Means algorithm; iii) “Scatter Plot” object which allows to plot clustering distribution.

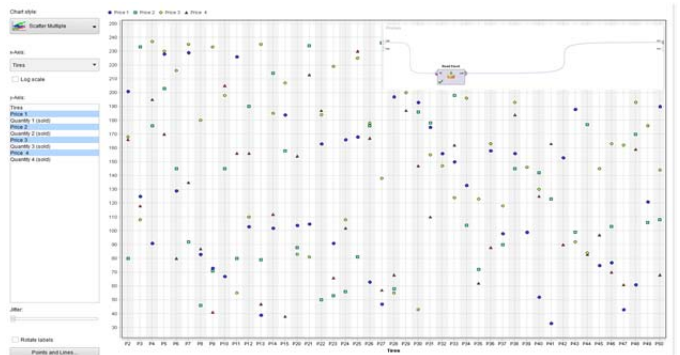

Fig. 14. Scatter Multiple plot of Rapid Miner tool. Inset: “Read Excel” object and related workflow.

In Fig. 15 is illustrated the KNIME workflow used for the k-Means analysis. The workflow is made by the following

Fig. 15. KNIME Workflow: k-Means algorithm.

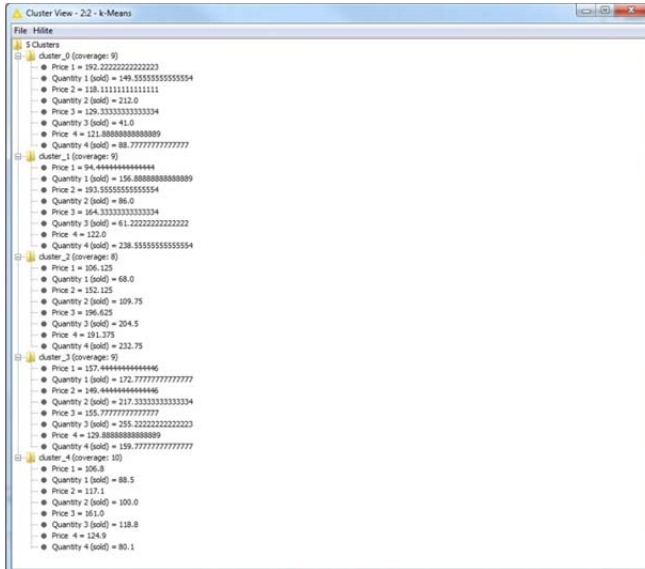

Fig. 16. KNIME: k-Means algorithm results

We focus now our attention on the key interpretation of results of Fig. 16 and Fig. 17, by considering a single tire model. For example the tire model P2 belongs to the cluster 0 (see first element of the plot of Fig. 17) which takes into account the 4 competitors prices and the sold quantities. Observing the data reported in Fig. 16 about the maximum quantity (quantity 2 parameter corresponding to 212), the best price to adopt for the tire P2 is provided by the parameter Price 2 (118.11 Euro). This is the decision support system to establish the best price by considering the high sold quantities and the competitor prices.

By considering tyres model P3 we observe that it belongs to cluster 1; the best price to adopt by observing high sold quantities (Quantity 4 =238.5) is Price 4 (122). This analysis procedure can be applied for each model type. We observe that the horizontal axis of Fig. 17 represents the tires types (Model P2, P3, P4, etc.), besides the vertical axis of Fig. 17 indicates the clusters (cluster 0, cluster 1, cluster 2, cluster 3, cluster 4)

Fig. 17. KNIME: clustering results.

In Fig. 18 we illustrates the clustering results in a table format, the lower and upper bound limits of clusters, and all clustering results. The data are viewed by the selecting the object of the node 2 of Fig. 15.

IV. CONCLUSION

The goal of this paper was to provide results of an industrial project oriented on intelligent dynamic tires price definition. The project includes smart mobile technologies and data mining processing able to improve a decision support system concerning tires price to adopt. In the paper were presented all the design steps, some tests validating the software implementation and clustering results. The best tires price were selected dynamically by observing during the time together sold quantities and competitors price. The data mining engine could be applied also for the sales and price predictions by implementing a linear regression algorithm [17] or Artificial Neural Networks – ANN- workflow based on time series forecasting approach [18].

ACKNOWLEDGMENT

The work has been developed in the frameworks of the Italian projects: “Modello dinamico di identificazione della tipologia e del prezzo ottimale dei pneumatici mediante applicazione web (Dynamic model for identifying the type and optimal price of tires through a web application): “Tires Detection and Dynamic Pricing”. Authors gratefully thanks Vito Custodero and Elisabetta Valenzano for their support in the realization of this work. special thanks are addressed to William Ciavarella for his knowledge in tires marketing.
